Short introduction Superconductivity Magnetic flux quantization Josephson junctions **SQUID**s

## Magnetic flux quantization in superconductors

The superconducting flux quantum was predicted by London (1948) using a phenomenological semiclasical model.

Superconductivity is a macroscopic quantum phenomenon.

 $\Psi = |\Psi| e^{i\theta}$  is the single superconducting wave function described all condensed collective of Cooper electron pairs (2e, 2m).  $|\Psi|^2 = n_S / 2$ 

 $p = 2mv_s + 2eA$  is the gauge-invariant momentum of Cooper pairs

Meissner effect in bulk superconductor

 $\lambda$  is the London penetration depth

$$\hbar \nabla \theta = 2m\kappa_s + 2eA$$

$$\hbar \oint \nabla \theta \, dl = 2e \oint A \, dl = \int \int B \, dS$$
  

$$2\pi n = (2e/\hbar) \Phi$$
  

$$\Phi = n\Phi_0$$
  
Magnetic flux quantum  

$$\Phi_0 = h/(2e) = 2.067833636 \times 10^{-15} \, \text{Wb}$$
  

$$(2.067833636 \times 10^{-7} \, \text{G cm}^2)$$

#### **Tunnel Josephson junction**

B.D. Josephson, 1962

 $I_s = I_c \sin \varphi$  Fully non-dissipative regime for  $I < I_c$ 

 $V = [\hbar /(2e)]d\phi/dt$ 

#### **Resistive-Capacitive Shunted Junction (RCSJ-model)**

 $I_{J}=I_{c} \sin\varphi - \text{"Josephson channel"} = \Phi_{0}/(2\pi)d\varphi/dt$   $I_{n}=V/R_{n} = [\Phi_{0}/(2\pi R_{n})]\varphi_{t} - \text{"resistive channel"}$   $I_{D}=CdV/dt = [\Phi_{0}C/(2\pi)]\varphi_{tt} - \text{"capacitive channel"}$   $I_{D}=CdV/dt = [\Phi_{0}C/(2\pi)]\varphi_{tt} - \text{"capacitive channel"}$   $I_{L}=I_{c}\Phi_{0}/2\pi$   $I_{c} \sin\varphi + [\Phi_{0}/(2\pi R_{n})]\varphi_{t} + [\Phi_{0}C/(2\pi)]\varphi_{tt} = I_{e} | *E_{J}/I_{c}$   $[\hbar/(2e)]^{2}C \varphi_{tt} + [\hbar/(2e)]^{2}R_{n}^{-1}\varphi_{t} + E_{J} \sin\varphi = E_{J} (I_{e}/I_{c})$ 

## Magnetic flux quanta in Josephson junctions

Meissner state destruction in type II superconductors

 $I_{I} = I_{c} sin\phi$  - "Josephson channel"  $\mathbf{I_n} = \mathbf{V}/\mathbf{R_n} = [\Phi_0/(2\pi \mathbf{R_n})] \boldsymbol{\varphi_t}$  - "resistive channel"  $\mathbf{I}_{\mathbf{D}} = Cd\mathbf{V}/dt = [\Phi_{\mathbf{0}}C/(2\pi)]\phi_{tt}$  - "capacitive channel"  $\mathbf{I}_{c} sin \boldsymbol{\varphi} + [\Phi_{0}/(2\pi R_{n})]\boldsymbol{\varphi}_{t} + [\Phi_{0}C/(2\pi)]\boldsymbol{\varphi}_{tt} = \mathbf{I}_{e}$  $|*E_I/I_c$  $[\hbar/(2e)]^{2}C \phi_{tt} + [\hbar/(2e)]^{2}R_{n}^{-1}\phi_{t} + E_{J} \sin \phi = E_{J} (I_{e}/I_{c})$ The pendulum motion equation  $J \phi_{++} + \eta \phi_{+} + m g l \sin \phi = M$ φ **Phase difference** Phase angle φ  $J=m l^2$  $\rightarrow$ Moment of inertia  $[\hbar /(2e)]^{2}C$  $\rightarrow$  $[\hbar /(2e)]^2 R_n^{-1}$ Viscosity coefficient η  $(\text{mg sin}\boldsymbol{\varphi})\boldsymbol{l}$  $\rightarrow$ **Restoring moment** (m g sin  $\varphi$ ) *l*  $E_{I} \sin \varphi$ Applied torque moment **T**  $\rightarrow$  $\mathbf{E}_{I}(\mathbf{I}/\mathbf{I}_{c})$ 

## Submicron tunnel junctions in normal state

Submicron-scale tunnel junction with small enough capacitance C. Single electron Coulomb (charging) energy  $E_{C} = \frac{e^2}{2C}$  is large.

**Q** is charge and  $\mathbf{E}_{c} = \mathbf{Q}^{2}/(2\mathbf{C}) = \mathbf{C}\mathbf{V}^{2}/2$  is energy of this capacitor.

Discharge of the capacitor is not favorable for some value Q: new energy  $\mathbf{E'_c} = (\mathbf{Q} - |\mathbf{e}|)^2 / (\mathbf{2C})$  becomes larger for  $\mathbf{0} < \mathbf{Q} < |\mathbf{e}|/2$ ! Coulomb blockade of tunneling for V: (V=Q/C)E' E 0 < V < |e|/(2C)~ 2 nm *The increase of the differential resistance* Q/e around zero bias is called the **Coulomb blockade**. -1/21/21.0 **Tunneling is** Limitation on T and R: prohibited E'\_-E\_>0 E<sub>c</sub>>kT (thermal fluctuations), C<10<sup>-15</sup> F,T>1 K 0.5-Region of  $1/R_T + 1/R_e < 1/R_O$  (quantum fluctuations) Coulomb Q/e= $\mathbf{R}_{\Omega} = h/(4e^2) \sim 6 \mathbf{k}\Omega$  is the quantum resistance blockade 0.0 0.5 0.0 VC/e

## Josephson junction in quantum limit

"Quantum Josephson junction" is a submicron-scale tunnel junction with small enough capacitance  $C \rightarrow 0$ .

By analogy with "Quantum pendulum": when  $m \rightarrow 0$  null oscillations arise,

**because**  $\Delta \phi \Delta \mathbf{M} \sim \hbar$ . ( $\phi=0$   $\mu$  M=0 without oscillations!)

 $M = J \phi_t$  is angular momentum.

Josephson junction angular momentum is  $M=J \ \phi_t = [\hbar \ /(2e)]^2 C \phi_t = [\hbar \ /(2e)] C \ V=Q[\hbar \ /(2e)]$ 

 $\Delta \phi \Delta \mathbf{Q} \sim 2\mathbf{e}$  or  $\Delta \phi \Delta \mathbf{n} \sim 1$ 

where **Q** is the junction (capacitor) charge,  $\mathbf{n} = \mathbf{Q}/(2\mathbf{e})$  is excess Cooper pairs. Quantum Josephson junctions have large Coulomb energy  $\mathbf{E}_{\mathbf{C}} \sim \mathbf{E}_{\mathbf{J}}$  due to small capacitance:  $\mathbf{E}_{\mathbf{C}} = (2\mathbf{e})^2/(2\mathbf{C})$ 

(Tunnel junctions with sizes smaller than  $0.3 \times 0.3 \ \mu m^2$ , C~10<sup>-15</sup>F) Thus total energy of the quantum Josephson junction is

 $E = (2e)^{2}/(2C) + E_{J} (1 - \cos \phi) - [\Phi_{0}/(2\pi)]I\phi$ 

# Thermal and quantum fluctuations of the critical current

The resistive state is observed at  $\mathbf{I}_c^* < \mathbf{I}_c = (2e/\hbar)\mathbf{E}_J$ due to thermal activation through the barrier  $\mathbf{U}_0(\mathbf{I})$ The rate of the thermo-activated decay is

$$\omega_{\rm T} = \omega({\rm I}) \exp(-\frac{{\rm U}_0({\rm I})}{k{\rm T}})$$

where  $\omega(I) = \omega_p [1 - (I/I_c)^2]^{1/4}; \quad \omega_p = (L_J C)^{-1/4}$ 

and  $U_0(I) = (4\sqrt{2/3}) E_J [1 - (I/I_c)]^{3/2}$ 

Quantum decay for "quantum" Josephson junctions

$$\omega_{Q} = a_{q}\omega(I) \exp(-\alpha \frac{U_{0}(I)}{\hbar\omega(I)})$$

(from ground state)

 $kT \rightarrow \hbar \omega(I)$ , the null oscillation energy

<sup>y</sup>U<sub>0</sub>(I)

1/2

#### Phase quantum fluctuations and macroscopic quantum coherence

The Coulomb blockade fixes the charge, reducing  $\triangle Q$ in the uncertainty relation  $\triangle \phi \triangle Q \sim 2e$  This means that the uncertainty (blurring) of the phase,  $\triangle \phi$ , increases.

### **Qubit is a quantum bit of information**

The simplest qubit is a single quantum particle with spin  $\frac{1}{2}$ 

17

## SUPERCONDUCTING QUBITS

- superconducting nanostructures

- microwave technique

2D-transmon (x-mon), readout by the coplanar (on-chip) resonator

#### **Superconducting flux qubit**

Digital bit

Quantum bit

qubit operation

#### Flux qubit spectrum

#### PULSE TECHNIQUES OF MICROWAVE MANIPULATIONS AND CONTROL OF QUBIT STATES

The result: a microwave pulse with a controlled amplitude, duration, and phase is applied to the qubit, allowing to manipulate the qubit state.

Readout: the z-projection of the qubit state is read by applying a reading pulse at the resonator frequency.

#### Single qubit state readout

The basis of the dispersive readout method: dispersive frequency shift of the resonator when the state of the qubit changes:

$$\Delta \omega_r = \pm \frac{\tilde{g}}{\omega_q - \omega_r}$$

 $\tilde{g}$  is effective coupling of resonator and qubit;  $\omega_q = \nu/\hbar$  is the qubit frequency;

 $\omega_r$  is the initial resonant frequency of the resonator

 $I_p$  is the current in the qubit ring

1	1	1	0

#### **GROVER SEARCH ALGORITHM DEMONSTRATION (2 QUBITS)**

In the simplest case of a two-qubit system with N = 4, one iteration (one appeal to the oracle) is sufficient, and the final state of the idealized system exactly coincides with the desired one

Oracle is an unitary operator U, which acts on the vectors x in the Hilbert space as follows:

$$\begin{cases} \widehat{U}(x = |a\rangle) = -|a\rangle \\ \widehat{U}(x \neq |a\rangle) = x \end{cases}$$

 $|a\rangle$  is the sought state

#### In general: $UU_s$ translates $|s\rangle$ to $|a\rangle$ with an accuracy of $\sim 1/\sqrt{N}!$

## GROVER SEARCH ALGORITHM DEMONSTRATION (results)

The blue columns indicate the number of different states being read for 10,000 runs. Database cells: |00>, |01>, |10>, |11>.

The red columns represent the results expected for an ideal (error-free) quantum computer, and the **black** dotted line represents a 50% probability (above the limit for a classical computer with a single Oracle call). *Measured probabilities* of correct execution of the state search algorithm:  $|00\rangle - 58\%$ ,  $|01\rangle - 57\%$ ,  $|10\rangle - 53\%$ ,  $\varkappa |11\rangle - 57\%$ .

#### **Two types of quantum computing devices**

- Analog devices (quantum simulators) are "direct" modeling of a specific material using an artificial quantum system. Fast search of system properties due to quantum parallelism (the system is simultaneously in all possible states, choosing the optimal one).
- More advanced algorithmic devices (universal quantum computers) finding the properties of the system through the use of quantum algorithms. They can be programmed like a regular computer. Not tied to a specific task.

# MULTIQUBIT STRUCTURE TECHNOLOGY
